Phishing Prevalence

- Of almost 2000 breaches in the 2017 Verizon DBIR report, 43% were the result of social attacks, 93% of which due to phishing¹
- 91% of attacks begin with phishing²

Phishing Techniques and Effectiveness

- Techniques include:
 - Malicious Links in emails
 - Attachments to emails
 - Soliciting information via email
- Phishing click rates of 10% or higher
- Targeted phishing was able to generate up to 54% click rates

Industry Phishing

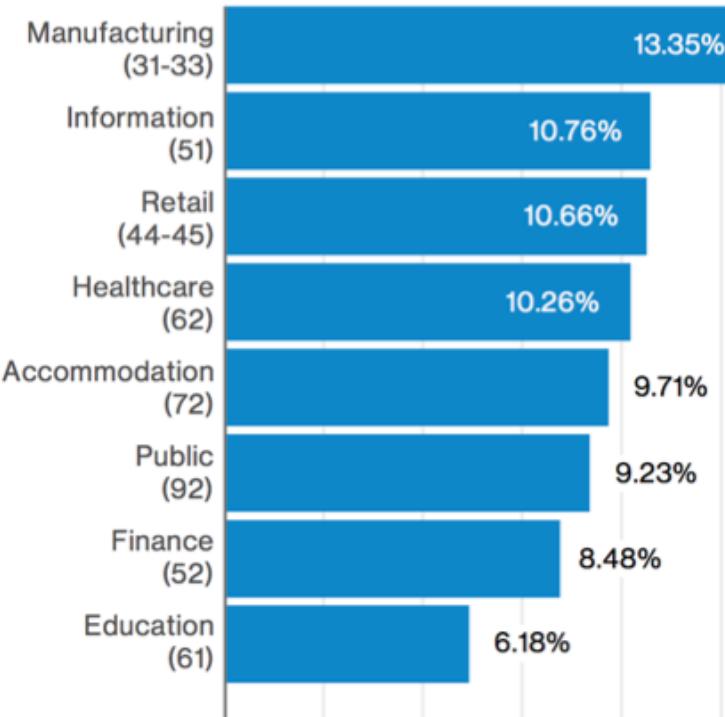

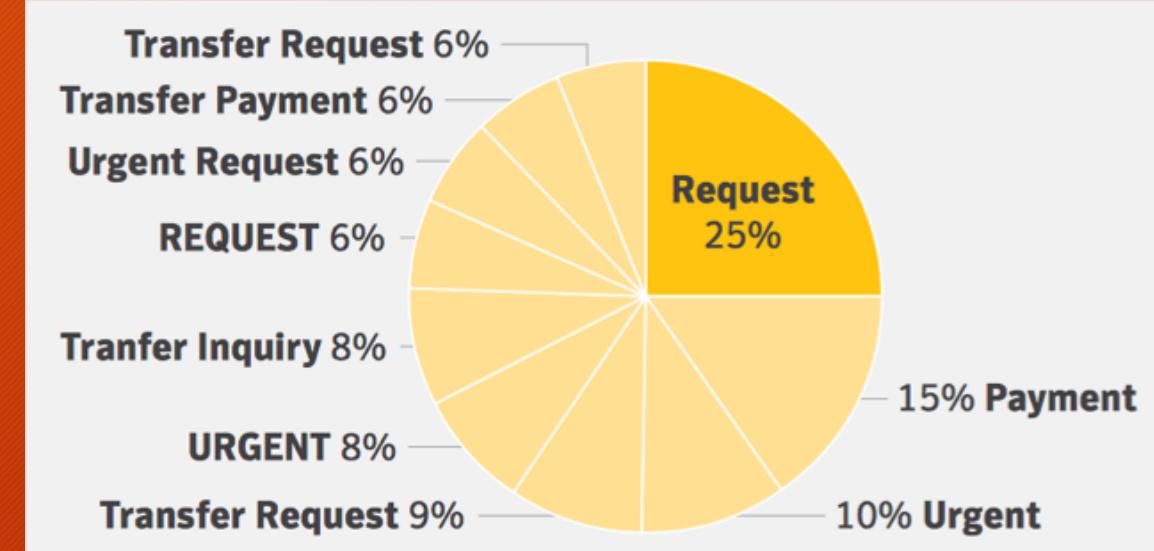

Figure 12: Median click rate per campaign by industry (n=7,153)

The lure

- Often a sense of action, urgency, or curiosity is used to entice people
- Others are crafted to the individual, sometimes creating fake online identities or websites

Spear phishing messages with malicious links

Definition

Emails with malicious links are designed to get a user to click on the link in order to deliver malware payloads.[\[1\]](#)[\[2\]](#)

Difficulty for the Adversary

Easy for the Adversary (Yes/No): Yes

Explanation: Sending emails is trivial and expected. The adversary needs to ensure links don't get tampered, removed, or flagged as a previously black-listed site.

Detection

Detectable by Common Defenses (Yes/No/Partial): Yes

Explanation: Defenders can implement mechanisms to analyze links and identify levels of concerns. However, the adversary has the advantage of creating new links or finding ways to obfuscate the link so that common detection lists can not identify it. Detection of a malicious link could be identified once the file has been downloaded.

Phishing in MITRE PRE-ATT&CK

The screenshot shows the MITRE PRE-ATT&CK website. The top navigation bar includes 'Page', 'Read', 'View form', 'View history', and a search bar. A sidebar on the left lists 'Main page', 'Contribute', 'References', 'Tactics' (with 'All Tactics', 'Priority Definition', 'Planning', and 'Priority Definition' listed), and 'Identification' (with 'People Weakness Identification', 'Organizational Weakness Identification', 'Adversary OPSEC', and 'Establish & Maintain Infrastructure' listed). The main content area displays the title 'Spear phishing messages with malicious links'. Below the title is a 'Definition' section: 'Emails with malicious links are designed to get a user to click on the link in order to deliver malware payloads.^{[1][2]}' To the right is a detailed view of the tactic: **Spear phishing messages with malicious links**, **Technique** PRE-T1146, **ID** Tactic, and **Tactic** Launch.

Explanation: Defenders can implement mechanisms to analyze links and identify levels of concerns. However, the adversary has the advantage of creating new links or finding ways to obfuscate the link so that common detection lists can not identify it. Detection of a malicious link could be identified once the file has been downloaded.

This screenshot shows the 'Detection' section of the tactic page. It includes a sub-section titled 'Detectable by Common Defenses (Yes/No/Partial): Yes' and an 'Explanation' block. The 'Explanation' block contains the same text as the one above: 'Defenders can implement mechanisms to analyze links and identify levels of concerns. However, the adversary has the advantage of creating new links or finding ways to obfuscate the link so that common detection lists can not identify it. Detection of a malicious link could be identified once the file has been downloaded.'

The Lure

Have a wonderful day,

The FedEx intl. team

Common Response

“Phishers will randomize credential harvesting links sent through email, making it even more difficult to implement blocks when email Sender and Subject correlations don’t detect all of the messages from a particular phishing campaign. As you search and sanitize, if you notice URL patterns begin to emerge, consider implementing Splunk RegEx searches to help fill in the gaps in your detections.”

Regular Expressions (RegEx) for Patterns

- Characters
 - [A-Za-z0-9] to match alpha-numeric characters
 - . Matches any single character
- Repeated Characters
 - * match the specified character zero or more times
 - {N, M} match the preceding character at least N and no more than M times

Regular Expressions (RegEx) for Patterns

- Characters
 - [A-Za-z0-9] to match alpha-numeric characters
 - . Matches any single character
- Repeated Characters
 - * match the specified character zero or more times
 - {N, M} match the preceding character at least N and no more than M times
- Examples:
 - [a-z]{1, 6}
 - *
 - [A-Z]\.php

would match the string “regex” but “Regex” would not
matches any string
matches a upper case letter followed by .php

Common Practitioner Response

New Search

```
daysago=30 index=web_proxy \.php\?id  
| regex url=".*/[a-zA-Z0-9]{5,15}/[a-zA-Z0-9]{5,15}\.php\?id=.*[a-zA-Z0-9]{1,15}@*[a-zA-Z0-9]{1,10}\.[a-z]{2,3}$"  
| table _time user url

Text Similarity

- Regular Expressions are one tool

Text Similarity

- Regular Expressions are one tool
- ...there are many others

Defender's Task

- Given some examples of what's malicious, find similar malicious examples in your own environment (if they exist)

Events in the millions,
billions, more (?) per day

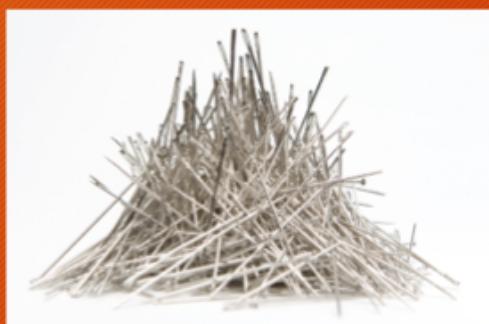

Relatively small volume
of true malicious events

Which set of tools to use?

- Needle in a haystack: given a handful of examples

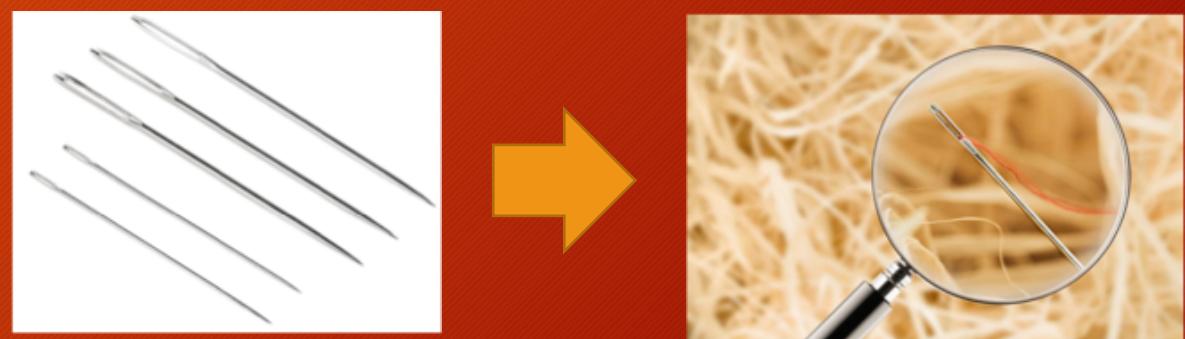

- Needle-stack of needles: I have thousands or more examples

Given a few needles, find a needle in a haystack

- Given a handful of examples, find similar examples in another environment
- String similarity
 - Levenshtein
 - Jaro
- Distance / similarity measurements
 - Cosine
 - Euclidean

String Distance / Similarity Measurements

- Levenshtein Distance (“Edit Distance”)
 - String metric representing the minimum number of edits e.g. insertions, deletions, and substitutions required to turn one string into another.
- Jaro Similarity
 - Measures several aspects of string similarity:
 - Number of matching characters
 - String length
 - Sequence of characters and transpositions

String Distance / Similarity Measurements

| String1 | String2 | Levenshtein | Jaro | Note |
|------------|-------------------|-------------|-------|--|
| google.com | google.com | 0 | 1.0 | Exact match |
| google.com | g00gle.com | 2 | 0.867 | Replace letter o with number zero |
| google.com | google.badguy.com | 7 | 0.863 | Subdomain mimicking legitimate registered domain |
| google.com | malware.ru | 9 | 0.533 | Completely unrelated |

Wikipedia. (2018). https://en.wikipedia.org/wiki/Levenshtein_distance

Wikipedia. (2018). https://en.wikipedia.org/wiki/Jaro%E2%80%93Winkler_distance

String Distance / Similarity Measurements

| String1 | String2 | Levenshtein | Jaro | Note |
|-----------|-----------|-------------|-------|------------------------------|
| bit | bot | 1 | 0.778 | Small change in short string |
| bitly.bit | bitly.bot | 1 | 0.926 | Small change in long string |

Text to Numeric Vector

- Many techniques only work with numbers as input, rather than text
- This requires transforming words into numbers

 - and more...

Naïve Bayes Example

Corpus

1. I loved the movie
2. I hated the movie
3. A great movie. A good movie.
4. Poor acting
5. Great acting, a good movie

| Doc | I | loved | the | movie | hated | a | great | poor | acting | good | label |
|-----|---|-------|-----|-------|-------|---|-------|------|--------|------|-------|
| #1 | 1 | 1 | 1 | 1 | | | | | | | + |
| #2 | 1 | | 1 | 1 | 1 | | | | | | - |
| #3 | | | | 2 | | 1 | 1 | | | 1 | + |
| #4 | | | | | | | | 1 | 1 | | - |
| #5 | | | | 1 | | 1 | 1 | | 1 | 1 | + |

Example for word “good”:

$$P(\text{"good"} | -) = (N_{k-} + 1) / (n_- + |\text{vocab}|) = 0.0625$$

$$P(\text{"good"} | +) = (N_{k+} + 1) / (n_+ + |\text{vocab}|) = 0.125$$

Example: What's the value of “I hated the poor acting”?

$$V(+) = P(+)\cdot P(I|+)\cdot P(hated|+)\cdot P(the|+)\cdot P(poor|+)\cdot P(acting|+) = 6.05 \cdot 10^{-7}$$

$$V(-) = P(-)\cdot P(I|-)\cdot P(hated|-)\cdot P(the|-)\cdot P(poor|-)\cdot P(acting|-) = 1.22 \cdot 10^{-5}$$

Questions

Naïve Bayes Example

Given these definitions...

N_{k+} = # times word K occurs in the + class

N_{k-} = # times word K occurs in the - class

$|\text{vocab}|$ = # unique words in vocabulary = 10

$P_+ = 3 / 5 = .6$

$P_- = 2 / 5 = .4$

n_+ = sum of word counts for that class = 14

n_- = sum of word counts for that class = 6

W_k = a word, like “loved”

...we get the probability of any word for its label

$P(W_k | +) = (N_{k+} + 1) / (n_+ + |\text{vocab}|)$

$P(W_k | -) = (N_{k-} + 1) / (n_- + |\text{vocab}|)$

Example for word “good”:

$$\begin{aligned} P(\text{"good"} | -) &= (N_{k-} + 1) / (n_- + |\text{vocab}|) \\ &= 0 + 1 / 6 + 10 = 1 / 16 = 0.0625 \end{aligned}$$

$$\begin{aligned} P(\text{"good"} | +) &= (N_{k+} + 1) / (n_+ + |\text{vocab}|) \\ &= (2 + 1) / (14 + 10) = 3 / 24 = 0.125 \end{aligned}$$

Example: What's the value of “I hated the poor acting”?

$$V(+) = P(+)\bar{P}(I|+)\bar{P}(\text{hated}|+)\bar{P}(\text{the}|+)\bar{P}(\text{poor}|+)\bar{P}(\text{acting}|+) = 6.05 \cdot 10^{-7}$$

$$V(-) = P(-)\bar{P}(I|-\bar{P}(\text{hated}|-\bar{P}(\text{the}|-\bar{P}(\text{poor}|-\bar{P}(\text{acting}|-) = 1.22 \cdot 10^{-5}$$

*Based on the Naïve Bayes model the sentence is more likely to be negative (-), since $1.22 \cdot 10^{-5}$ is bigger than $6.05 \cdot 10^{-7}$.
